Today

- ISA Design
- With specific RISC-V examples
- Project 1 intro in last 10-15 minutes
- RISC-V “Green Sheet” ISA Summary available on Canvas

- Reminder: Asmt 2 due Friday Sept 12 at 6pm ET

ICQs from last time

- *Key Takeaways:*
  - ”smaller is faster, chip design has developed massively but the main principles from Von Neumann remain. Also learnt about state vs combinatorial”
  - “Loved hearing about how muxes work”
  - “How understanding the logic behind instructions is enough to piece together how the elements of a CPU are connected.”
  - “ISA affects implementation of software”
  - “Smaller is faster I used register files in 206 but didn’t understand why we preferred that to memory until now”
- *Purpose of EDSAC Diagram, Datapath, Examples:*
  - Teaching Goal: To use a very simple ISA to introduce design process. Think of it as an initial foundation -- Everything we’ve done in EDSAC we will reinforce by doing again in more detail with RISC-V (and more).
- *RISC-V*
  - Note from MRM: RISC-V originated for academic research use, **but now IS widely used in industry**
    - Western Digital and Seagate have been using RISC-V cores in controllers for their hard disk drives (HDDs) and solid-state drives (SSDs) for years.
    - Industrial control systems, IoT devices, AmazFit Smart watches,
    - Datacenter, Automotive…

ICQs from last time

- If it's been a while since taking COS 217 and we didn't take ECE 206 what should we do in preparation for Hw and assignments?
  - Lectures heavily coincide with textbook material. The best additional prep is to read the portions of the textbook that go with each lecture/assignment.

- ICQ Input on Pace of class:
  - Some say a little too fast, some say too slow, and many say just right.

ISA **Design**

Chapter 2

RISC-V at a glance

RISC-V operands

Name	Example	Comments
32 registers	x0-x31	Fast locations for data. In RISC-V, data must be in registers to perform arithmetic. Register x0 always equals 0.
2^{30} memory words	Memory[0], Memory[4], ..., Memory[4,294,967,292]	Accessed only by data transfer instructions. RISC-V uses byte addresses, so sequential word accesses differ by 4. Memory holds data structures, arrays, and spilled registers.

- RV32 and RV64 are two variants. This class will focus on RV64, where the default register size is 64 bits.

RISC-V at a glance

RISC-V assembly language

Category	Instruction	Example	Meaning	Comments
Arithmetic	Add	`add x5, x6, x7`	`x5 = x6 + x7`	Three register operands; add
	Subtract	`sub x5, x6, x7`	`x5 = x6 - x7`	Three register operands; subtract
	Add immediate	`addi x5, x6, 20`	`x5 = x6 + 20`	Used to add constants
Data transfer	Load word	`lw x5, 40(x6)`	`x5 = Memory[x6 + 40]`	Word from memory to register
	Load word, unsigned	`lwu x5, 40(x6)`	`x5 = Memory[x6 + 40]`	Unsigned word from memory to register
	Store word	`sw x5, 40(x6)`	`Memory[x6 + 40] = x5`	Word from register to memory
	Load halfword	`lh x5, 40(x6)`	`x5 = Memory[x6 + 40]`	Halfword from memory to register
	Load halfword, unsigned	`lhu x5, 40(x6)`	`x5 = Memory[x6 + 40]`	Unsigned halfword from memory to register
	Store halfword	`sh x5, 40(x6)`	`Memory[x6 + 40] = x5`	Halfword from register to memory
	Load byte	`lb x5, 40(x6)`	`x5 = Memory[x6 + 40]`	Byte from memory to register
	Load byte, unsigned	`lbu x5, 40(x6)`	`x5 = Memory[x6 + 40]`	Byte unsigned from memory to register
	Store byte	`sb x5, 40(x6)`	`Memory[x6 + 40] = x5`	Byte from register to memory
	Load reserved	`lr.d x5, (x6)`	`x5 = Memory[x6]`	Load; 1st half of atomic swap
	Store conditional	`sc.d x7, x5, (x6)`	`Memory[x6] = x5; x7 = 0/1`	Store; 2nd half of atomic swap
	Load upper immediate	`lui x5, 0x12345`	`x5 = 0x12345000`	Loads 20-bit constant shifted left 12 bits
Logical	And	`and x5, x6, x7`	`x5 = x6 & x7`	Three reg. operands; bit-by-bit AND
	Inclusive or	`or x5, x6, x8`	`x5 = x6 | x8`	Three reg. operands; bit-by-bit OR
	Exclusive or	`xor x5, x6, x9`	`x5 = x6 ^ x9`	Three reg. operands; bit-by-bit XOR
	And immediate	`andi x5, x6, 20`	`x5 = x6 & 20`	Bit-by-bit AND reg. with constant
	Inclusive or immediate	`ori x5, x6, 20`	`x5 = x6 | 20`	Bit-by-bit OR reg. with constant
	Exclusive or immediate	`xori x5, x6, 20`	`x5 = x6 ^ 20`	Bit-by-bit XOR reg. with constant
Shift	Shift left logical	`sll x5, x6, x7`	`x5 = x6 << x7`	Shift left by register
	Shift right logical	`srl x5, x6, x7`	`x5 = x6 >> x7`	Shift right by register
	Shift right arithmetic	`sra x5, x6, x7`	`x5 = x6 >> x7`	Arithmetic shift right by register
	Shift left logical immediate	`slli x5, x6, 3`	`x5 = x6 << 3`	Shift left by immediate
	Shift right logical immediate	`srli x5, x6, 3`	`x5 = x6 >> 3`	Shift right by immediate
	Shift right arithmetic immediate	`srai x5, x6, 3`	`x5 = x6 >> 3`	Arithmetic shift right by immediate
Conditional branch	Branch if equal	`beq x5, x6, 100`	`if (x5 == x6) go to PC+100`	PC-relative branch if registers equal
	Branch if not equal	`bne x5, x6, 100`	`if (x5 != x6) go to PC+100`	PC-relative branch if registers not equal
	Branch if less than	`blt x5, x6, 100`	`if (x5 < x6) go to PC+100`	PC-relative branch if registers less
	Branch if greater or equal	`bge x5, x6, 100`	`if (x5 >= x6) go to PC+100`	PC-relative branch if registers greater or equal
	Branch if less, unsigned	`bltu x5, x6, 100`	`if (x5 < x6) go to PC+100`	PC-relative branch if registers less, unsigned
	Branch if greater or equal, unsigned	`bgeu x5, x6, 100`	`if (x5 >= x6) go to PC+100`	PC-relative branch if registers greater or equal, unsigned
Unconditional branch	Jump and link	`jal x1, 100`	`x1 = PC+4; go to PC+100`	PC-relative procedure call
	Jump and link register	`jalr x1, 100(x5)`	`x1 = PC+4; go to x5+100`	Procedure return; indirect call

"Green Sheet" available on top of Canvas page.
VERY USEFUL SUMMARY!

Arithmetic Operations

- Add and subtract, three operands
  - All operands are registers. No MEMORY operands!
  - Two source registers and one destination register

```
add a, b, c  // a gets b + c
```

- All arithmetic operations have this form
- *Design Principle 1:* Simplicity favors regularity
  - Regularity makes implementation simpler
  - Simplicity enables higher performance at lower cost

Register Operands

- Arithmetic instructions use register operands. CANNOT use memory operands!

- RISC-V has a 32-entry register file
  - Use for frequently accessed data
  - 64-bit data is called a “doubleword”
    - 32 x 64-bit general purpose registers x0 to x31
  - 32-bit data is called a “word”
  - RV64 == 32 entries of 64 bits apiece

- *Design Principle 2:* Smaller is faster
  - c.f. main memory: millions of locations.
  - Register files are smaller and closer and therefore faster to access!

RISC-V Registers

- x0: the constant value 0
- x1: return address
- x2: stack pointer
- x3: global pointer
- x4: thread pointer
- x5 – x7, x28 – x31: temporaries
- x8: frame pointer
- x9, x18 – x27: saved registers
- x10 – x11: function arguments/results
- x12 – x17: function arguments

Register Operand Example

- C code:

```
f = (g + h) - (i + j);
```

- Compiled RISC-V code?

Register Operand Example

- C code:

```
f = (g + h) - (i + j);
```

  - f, …, j in x19, x20, …, x23

- Compiled RISC-V code:

```
add x5, x20, x21
add x6, x22, x23
sub x19, x5, x6
```

Memory Operands

- Main memory used for larger/composite data
  - Arrays, structures, dynamic data
- To apply arithmetic operations
  - Load values from memory into registers
  - Store result from register to memory
- Memory is byte addressed
  - Each address identifies an 8-bit byte
- In the weeds:
  - RISC-V does not require words to be aligned in memory
    - Unlike some other ISAs
  - RISC-V is Little Endian
    - Least-significant byte at least address of a word
    - *c.f.* Big Endian: most-significant byte at least address

Memory Operand Example

- C code:

  `A[12] = h + A[8];`

  – h in x21, base address of A in x22

  – A is an array of type “long long” meaning elements are 64-bit integers

- Compiled RISC-V code:

Memory Operand Example

- C code:

  ```
  A[12] = h + A[8];
  ```

  - h in x21, base address of A in x22
  - A is an array of type “long long” meaning elements are 64-bit integers
- Compiled RISC-V code:
  - Index 8 requires offset of 64
    - 8 bytes per doubleword

```
ld   x9, 64(x22)
add  x9, x21, x9
sd   x9, 96(x22)
```

Registers vs. Memory

- Registers are faster to access than memory
- Operating on memory data requires loads and stores
  - More instructions to be executed
- Compiler must use registers for variables as much as possible
  - Only spill to memory for less frequently used variables
  - Register optimization is important!

Immediate Operands

- Constant data specified in an instruction

```
addi x22, x22, 4
```

- Make the common case fast
  - Small constants are common
  - Immediate operand avoids a load instruction

Software Perspective

- Say you're a compiler, and the code is trying to double x22 and put that result back in x22. What are different instruction(s) by which you might achieve that?

Expressing and Representing Numbers

(Review – study on your own)

Unsigned Binary Integers

- Given an n-bit number

$$x = x_{n-1}2^{n-1} + x_{n-2}2^{n-2} + \cdots + x_1 2^1 + x_0 2^0$$

- Range: 0 to $+2^n - 1$
- Example
  - $0000\ 0000 \ldots 0000\ 1011_2$
    $= 0 + \ldots + 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0$
    $= 0 + \ldots + 8 + 0 + 2 + 1 = 11_{10}$
- Using 64 bits: 0 to +18,446,774,073,709,551,615

2s-Complement Signed Integers

- Given an n-bit number

$$x = -x_{n-1}2^{n-1} + x_{n-2}2^{n-2} + \cdots + x_1 2^1 + x_0 2^0$$

- Range: -2^{n-1} to $+2^{n-1} - 1$
- Example
  - $1111\ 1111\ \ldots\ 1111\ 1100_2$
    $= -1 \times 2^{31} + 1 \times 2^{30} + \ldots + 1 \times 2^2 + 0 \times 2^1 + 0 \times 2^0$
    $= -2{,}147{,}483{,}648 + 2{,}147{,}483{,}644 = -4_{10}$
- Using 64 bits: −9,223,372,036,854,775,808
  to 9,223,372,036,854,775,807

2s-Complement Signed Integers

- Bit 63 is sign bit
  - 1 for negative numbers
  - 0 for non-negative numbers
- $-(-2^{n-1})$ can't be represented
- Non-negative numbers have the same unsigned and 2s-complement representation
- Some specific numbers
  - 0: 0000 0000 … 0000
  - –1: 1111 1111 … 1111
  - Most-negative: 1000 0000 … 0000
  - Most-positive: 0111 1111 … 1111

Signed Negation

- Complement and add 1
  - Complement means 1 → 0, 0 → 1

$$x + \bar{x} = 1111...111_2 = -1$$

$$\bar{x} + 1 = -x$$

- Example: negate +2
  - +2 = 0000 0000 … 0010_{two}
  - –2 = 1111 1111 … 1101_{two} + 1
    = 1111 1111 … 1110_{two}

Sign Extension

- Representing a number using more bits
  - Preserve the numeric value
- Replicate the sign bit to the left
  - c.f. unsigned values: extend with 0s
- Examples: 8-bit to 16-bit
  - +2: 0000 0010 => 0000 0000 0000 0010
  - –2: 1111 1110 => 1111 1111 1111 1110

- In RISC-V instruction set
  - `lb`: sign-extend loaded byte
  - `lbu`: zero-extend loaded byte

Representing and Encoding Instructions

Representing Instructions

- Instructions are encoded in binary
  - Called machine code

- RISC-V instructions
  - Encoded as 32-bit instruction words
  - Small number of formats encoding operation code (opcode), register numbers, …
  - Regularity!

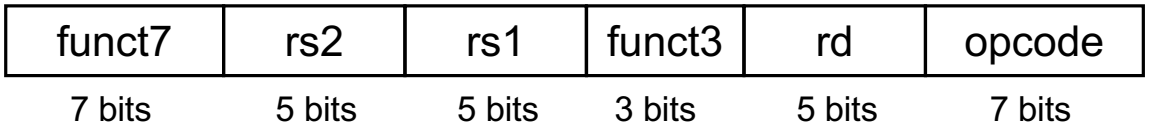
Hexadecimal

- Base 16
  - Compact representation of bit strings
  - 4 bits per hex digit

0	0000	4	0100	8	1000	c	1100
1	0001	5	0101	9	1001	d	1101
2	0010	6	0110	a	1010	e	1110
3	0011	7	0111	b	1011	f	1111

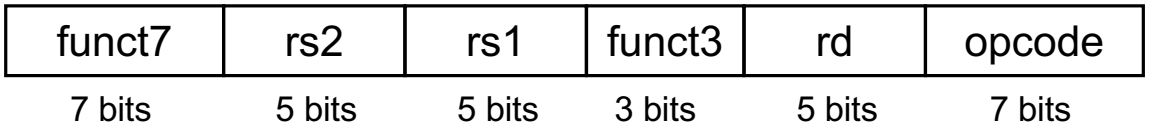
- Example: eca8 6420
  - 1110 1100 1010 1000 0110 0100 0010 0000

RISC-V R-format Instructions



- Instruction fields
  - opcode: operation code
  - rd: destination register number
  - funct3: 3-bit function code (additional opcode)
  - rs1: the first source register number
  - rs2: the second source register number
  - funct7: 7-bit function code (additional opcode)

R-format Example



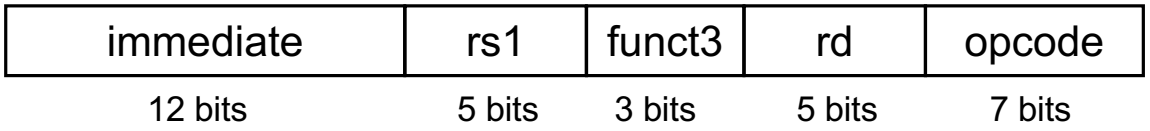
funct7	rs2	rs1	funct3	rd	opcode
7 bits	5 bits	5 bits	3 bits	5 bits	7 bits

```
add x9,x20,x21
```

0	21	20	0	9	51
0000000	10101	10100	000	01001	0110011

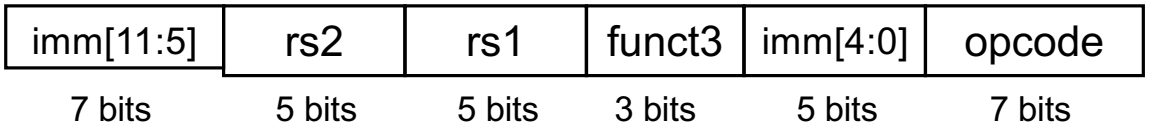
$0000\ 0001\ 0101\ 1010\ 0000\ 0100\ 1011\ 0011_{two} =$
$015A04B3_{16}$

RISC-V I-format Instructions



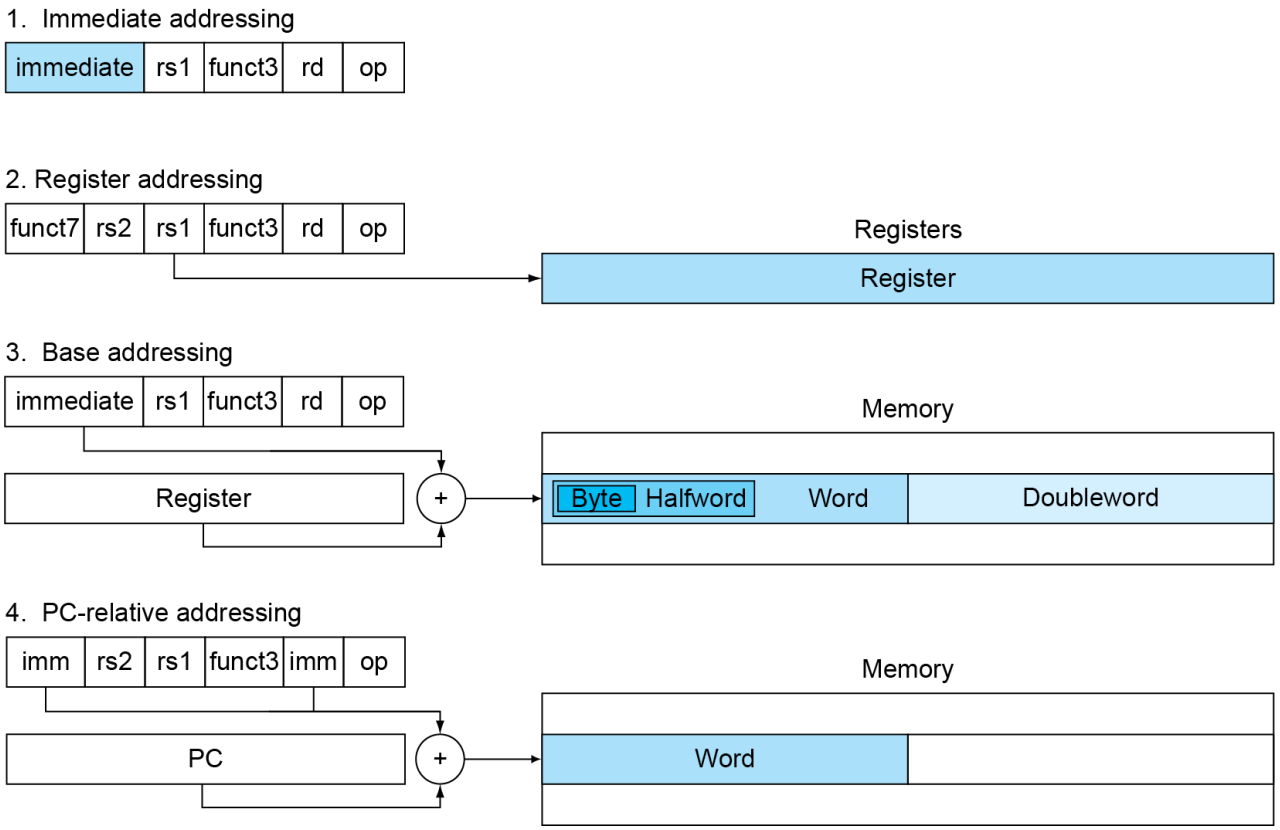
- Immediate arithmetic and load instructions
  - rs1: source or base address register number
  - immediate: constant operand, or offset added to base address
    - 2s-complement, sign extended
- *Design Principle 3:* Good design demands good compromises
  - Different formats complicate decoding, but allow 32-bit instructions uniformly
  - Keep formats as similar as possible

RISC-V S-format Instructions



- Different immediate format for store instructions
  - rs1: base address register number
  - rs2: source operand register number
  - immediate: offset added to base address
    - Split so that rs1 and rs2 fields always in the same place

RISC-V Addressing Summary



RISC-V Encoding Summary

Name (Field Size)	Field 7 bits	5 bits	5 bits	3 bits	5 bits	7 bits	Comments
R-type	funct7	rs2	rs1	funct3	rd	opcode	Arithmetic instruction format
I-type	immediate[11:0]		rs1	funct3	rd	opcode	Loads & immediate arithmetic
S-type	immed[11:5]	rs2	rs1	funct3	immed[4:0]	opcode	Stores
SB-type	immed[12,10:5]	rs2	rs1	funct3	immed[4:1,11]	opcode	Conditional branch format
UJ-type	immediate[20,10:1,11,19:12]				rd	opcode	Unconditional jump format
U-type	immediate[31:12]				rd	opcode	Upper immediate format

Example: Encoding Instructions

- Constant data specified in an instruction

  ```
  addi x22, x22, 4
  ```

- Binary encoding per RISC-V formats?

Design Variations: Take a Side!

- Suppose you were one of the designers of the original RISC-V instruction set. You have an idea:
- Your idea is to make program code fit into smaller memories by having some of the instructions be encoded into just 16-bits, while most of the rest of the instructions still use 32-bits.

1) Propose a format for these instructions and propose 3 specific new instructions to use it.

2) Be ready to take a side:

For the 16-bit formats or

Against this addition---why might it be a good or bad idea?
